## Lecture 13: Search-to-Decision, Padding, Dichotomy Theorems

Marcythm

July 16, 2022

### 1 Lecture Notes

What we are going to do:

1. Deciding SAT is hard. Is searching even harder?
2. Maybe  $\text{SAT} \notin \text{P}$ , how fast can we solve it?
3.  $\text{LIS} \in \text{P}$ , even  $\in \text{TIME}(n^2)$ . Is it  $\in \text{TIME}(n^{1.9})$ ?
4. Other resources (e.g. space, random interaction)?
5.  $2\text{SAT} \in \text{P}$ ,  $3\text{SAT}$  NP-complete. Why?
6. Is every  $L \in \text{NP}$  either  $\in \text{P}$  or NP-complete?
7. Maybe SAT “almost in” P?

Suppose  $\text{P} = \text{NP}$ , then  $\text{CIRCUIT-SAT} \in \text{P}$ , exists poly-time algo  $M_{\text{CSAT}}$  s.t.

$$M_{\text{CSAT}}(C) = \begin{cases} \text{yes,} & \text{if } C \text{ is satisfiable} \\ \text{no,} & \text{if } C \text{ is not satisfiable} \end{cases}$$

then we can decide a satisfying assignment bit-by-bit.

For  $3\text{COL}$ , the subinstance to find solution is  $3\text{COL} + \text{UNARY}$  in homework 6.

$\text{CSAT}$  is “downward” self-reducible.

**Theorem 1.1.** Suppose  $L \in \text{NP}$ , with verifier  $V(x, y)$ . Assume  $\text{P} = \text{NP}$ , then exists poly-time algo  $S$  s.t.  $\forall x \in L, V(x, S(x))$  accepts.

*Proof.* Use the idea of Cook-Levin Theorem. Given  $x \in L$ , construct a circuit  $C_x(y)$  that does the same as  $V(x, y)$ . Then  $S(x) = C(x, y)$  is a solution.  $\square$

A complexity theory “trick”: padding

**Theorem 1.2.**  $\text{P} = \text{NP} \implies \text{EXP} = \text{NEXP}$  (contrapositive:  $\text{EXP} \neq \text{NEXP} \implies \text{P} \neq \text{NP}$ )

*Proof.* Assume  $\text{P} = \text{NP}$ , need to show  $\text{NEXP} \subseteq \text{EXP}$ . Let  $L \in \text{NEXP}$ , say  $M$  is a nondet TM deciding  $L$  in time  $2^{n^k}$ . Let  $L_{\text{pad}} = \{\langle x, 1^{2^{|x|^k}} \rangle : x \in L\}$ .

**Claim 1.3.**  $L_{\text{pad}} \in \text{NP}$ .

*Proof.* Define  $M'$  a nondet TM. Given input  $y$ , it first check if  $y = \langle x, 1^{2^{|x|^k}} \rangle$  in time about  $O(|y|)$ , then throws away 1s, gets  $x$ , and simulate nondet  $M(x)$  in time  $O(2^{n^k}) = O(|y|)$ .  $\square$

Then  $L_{\text{pad}} \in \text{P}$ . Let  $A$  be poly-time algo deciding  $L_{\text{pad}}$ .

**Claim 1.4.**  $L \in \text{EXP}$ .

*Proof.* Let  $A'$  be TM with input  $x$ , it runs  $A(\langle x, 1^{2^{|x|^k}} \rangle)$  in time  $O(\text{poly}(2^{|x|^k}) = 2^{O(n^k)})$ , i.e.  $A'$  is in exponential time, so  $L \in \text{EXP}$ . □

□

1. World 1:  $\text{NP} = \text{P} + \text{NP-hard} + \text{something else}$
2. World 2:  $\text{NP} = \text{P} + \text{NP-hard}$
3. World 3:  $\text{P} = \text{NP}$

**Theorem 1.5** (Schaefer's Dichotomy Theorem '78). *Every boolean CSP is either in P (basically 2SAT, XOR-SAT, Horn-SAT) or NP-complete (everything else).*

**Theorem 1.6** (Bulatov '06). *Same theorem for ternary CSP, i.e.  $|D| = 3$ . e.g. 3-COL.*

**Conjecture 1.7** (Dichotomy Conjecture). *Every CSP is either in P or NP-complete.*

upcoming: a theorem that shows world 2 is generally impossible.

**Theorem 1.8** (Ladner's Theorem). *Assume  $\text{P} \neq \text{NP}$ , then  $\exists L \in \text{NP}$  s.t.  $L \notin \text{P}$  and  $L$  is not NP-complete.*

such  $L$ s are mostly unnatural. Maybe a natural  $L$ : GRAPH-ISOMORPHISM. Fastest algo is  $\text{TIME}(n^{\log^{10} n})$  (Babai '16).
