1 Lecture Notes

recall: $\Sigma_1 P = NP$, $\Pi_1 P = coNP$, $\Sigma_0 P = \Pi_0 P = P$, $PH = \bigcup_{k \in \mathbb{N}} \Sigma_k P = \bigcup_{k \in \mathbb{N}} \Pi_k P$ (different notations)

Theorem 1.1. $NP = P \implies PH = P$.

Proposition 1.2. $MC \in \Pi_2 P$, where MC means MINIMUM-CIRCUIT.

Proof. Given C , $\langle C \rangle \in MC \iff \forall \langle C' \rangle, |C'| < |C| : \exists y, |y| = \# \text{ inputs to } C, C' : C(y) \neq C'(y)$. The innermost statement $C(y) \neq C'(y)$ is what the verifier V checks. \square

Corollary 1.3. $NP = P (\iff SAT \in P) \implies MC \in P$.

Proof. For fixed C, C' what left to decide? “ $\exists y : C(y) \neq C'(y)$ ”, which is known as DCF (Different Circuit Functionality problem) in hw4: $DCF \in NP$. By assumption $DCF \in P$, so exists poly-time deterministic TM A deciding DCF. Now $\langle C \rangle \in MC \iff \forall \langle C' \rangle, |C'| < |C| : \langle C, C' \rangle \in DCF \iff \forall \langle C' \rangle : A(\langle C, C' \rangle)$ accepts. Reverse the accept/reject condition, we get $MC \in coNP \implies \overline{MC} \in NP \implies \overline{MC} \in P \implies MC \in P$. \square

Suppose we can solve SAT efficiently, we can solve a bunch of problems (3COL, UNSAT, HAMPATH, etc.) efficiently, also ...MIN-CIRCUIT?

ketpoint: Having a black box solving a problem is not as good as having the code for the problems.

To formalize “pesudocode” with an unimplemented `SolveSAT()` function:

Definition 1.4. A SAT-oracle TM is a TM with an extra power: an r/w “oracle tape”, and an extra instruction “ORACLE”. When operating ORACLE instruction, if oracle tape contains y , it’s replaced by “1” if $y \in SAT$, and “0” if $y \notin SAT$, with a cost of only 1 step.

Definition 1.5. More generally, we can define a B -oracle TM for every language B .

Definition 1.6. $P^{SAT} = \{L : L \text{ solvable in poly-time by a SAT-oracle TM}\}$.

e.g. $NP \subseteq P^{SAT}$, $coNP \subseteq P^{SAT}$, $CHROMATIC4 \in P^{SAT}$, but MINIMUM-CIRCUIT may not in P^{SAT} .
 $P^B \subseteq P^{SAT}$ if $B \in NP$, and $P^B = P^{SAT}$ if B is NP-complete (also for coNP-complete).

Notation 1.7. $P^{NP} = P^{SAT}$.

Definition 1.8 (Turing reduction (Cook reduction)). $A \leq_T^P B$ if $A \in P^B$.

Theorem 1.9. $P^{NP} \subseteq \Sigma_2 P$.

Proof. Assume $L \in P^{NP}$ solved by poly-time SAT-oracle TM A , need poly-time verifier $V(x, u_1, u_2)$ s.t. $x \in L \iff A(x) \text{ acc} \iff \exists u_1 \forall u_2 V(x, u_1, u_2) \text{ acc}$. Here

$u_1 = \langle \text{answers (and satisfying assignments if satisfiable) to } A(x) \text{'s oracle queries} \rangle$

$u_2 = \langle \text{some assignments for those unsatisfiable } \phi \text{ in } u_1 \rangle$

$V(x, u_1, u_2)$ checks those satisfying assignments in u_1 , and checks all the assignments given in u_2 cannot satisfy the corresponding ϕ s, then simulates $A(x)$. \square

Corollary 1.10. $co-P^{NP} = P^{NP}$, so $P^{NP} \subseteq \Pi_2 P$.
